Title of the Invention:

FIBER OPTIC VIDEO TRANSMITTER AND RECEIVER SYSTEM

00576484-052300

0 **FIBER OPTIC VIDEO TRANSMITTER AND RECEIVER SYSTEM**

FIELD OF THE INVENTION

5 This invention relates to transmitters for sending
uncompressed digital video signals from an originating device
such as a digital video camera to a distant location, such as a
studio or editing facility and receivers for receiving signals
sent from a distant location.

10 **BACKGROUND OF THE INVENTION**

15 In the past, video cameras or other sources of video imagery
produced analog signals that were passed on to monitors, editing
stations, post production, etc. via coaxial cables. With the
advent of digital video cameras, and other devices transmitting a
high quality digital video signal, coaxial cables are often
unsatisfactory. Significant signal degradation occurs when the
distance between the source and the user of the signal is over
100 meters. Fiber optic systems have been used to transmit a
variety of analog and digital signals. Typically, these signals
20 involve a number of technologies, including broadcast quality
video cameras, broadcast remote digital video broadcasting
systems including drop distribution, post production point-to-
point links, studio matrix digital video switching networks,

0 serial digital interface video transport for high definition
television, high quality radiology and other medical systems,
sports, special events, studio broadcast programming, etc.

Prior digital image transmitting systems have been quite
limited and specialized. For example, Lang in U.S. Patent No.
5 5,164,839 describes a system for storing compressed digital video
source information on magnetic media, then transmitting it to a
remote VCR over a fiber optic cable. This system is limited in
video rate transmission and degrades signal quality through
compression.

10 Transmitting telephone signals via fiber optics is described
by Schussler in U.S. Patent No. 4,441,180. A multiplexing system
for simultaneously transmitting a number of signals over a fiber
optic system is described by Bell in U.S. Patent No. 4,061,577.
Kostreski, in U.S. Patent No. 5,534,912, describes a "video on
15 demand" system which transmits video signals over fiber optics.

Prior systems such as these do not provide the ideal
combination of functions that will provide transmission over
longer distances without signal degradation and avoiding
compression, will comply with requirements of serial digital
20 interface (SDI), digital video broadcasting (DVB) and high

0 definition television (HDTV) systems and provide flexibility in
furnishing a variety of data rates with automatic lock-on.

Thus, there is a continuing need for improved fiber optic
cable transmitters and receivers for use with uncompressed
digital signals from broadcast cameras and the like, which
5 permits transmission up to about 350 meters with automatic cable
equalization and a communications link up to about 40 kilometers
without significant signal degradation, utilize an uncompressed
digital signal for optimum quality, will automatically lock on
any of a plurality of data rates, and provide status indicators
10 for power regulation, signal strength, data rate and serial
digital interface lock/unlock.

SUMMARY OF THE INVENTION

00576484-052300
15 The above-noted capabilities, and others, are provided in
accordance with this invention which, basically, includes a
transmitter for receiving a digital video signal from a source,
such as a video camera, and transmitting the signal via an
optical fiber and a receiver for receiving the signal from the
optical fiber and preparing the signal for use in any desired
20 manner, such as broadcast transmission, editing, etc.

0 The transmitter basically comprises an equalizer which
performs automatic gain control and cable matching to 75 ohms
coaxial cable that receives an input signal from a source, such
as a digital video camera via a standard 75 ohm coaxial cable.
The equalized data signal is passed to a reclocker for
5 synchronization, decoding and reclocking to predetermined
standard signals. Synchronization, for the purposes of this
application comprises stabilizing the clock, retiming data
signals, correcting for incoming signal jitter, etc. and
otherwise cleaning up the signal. The signal is then passed to a
10 laser transmitter where a digital optical signal is introduced
into a fiber optic cable.

Meanwhile, the equalized signal from the equalizer is passed
to a signal level detector. A second output signal from the
reclocker is passed to the data rate and level encoder, which
15 activates a Circuit Board Indicator (CBI) driver to provide
visual indication of the data rate, signal level and power on or
off. A 5v power regulator is included to provide power at that
level to the system components.

The receiver basically comprises a laser detector that
20 receives the encoded laser signal from the fiber optic converts
it to an electrical signal and transmits the signal to a

0 reclocker for synchronization. The synchronized signal then goes
to a 75 ohms Video Driver and then passed through coaxial cable
to a monitor or other system that will use the signal. A 5v power
regulator is also provided. Meanwhile, a second signal from the
5 driver which will display a visual indication of operating
parameters, including the data rate in use, and power on/off,
whether the incoming signal is locked or unlocked.

10 The transmitter and receiver are each contained in a small
module that can be easily secured to operating equipment, such a
broadcast digital video camera or editing equipment.
Alternatively, a plurality of modules may be mounted in a 19"
rack for convenient operation and observation of the operating
parameter indicators.

15 **BRIEF DESCRIPTION OF THE DRAWING**

Details of the invention, and of preferred embodiments
thereof, will be further understood upon reference to the
drawing, wherein:

20 Figure 1 is a block diagram of the fiber optic video
transmitter of this invention;

0 Figure 2 is a block diagram of the fiber optic video receiver of this invention;

Figure 3 is a perspective view of the transmitter;

Figure 4 is an elevation view of the back of the transmitter;

5 Figure 5 is a perspective view of the receiver; and

Figure 6 is an elevation view of the back of the receiver.

DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS Figure 1 is a block diagram of the transmitter 10 for transmitting a video signal through a fiber optic.

10 A video signal from a source 12 such as a video camera is received via a conventional 75 ohm coaxial cable 14 or the like. That signal is passed to a cable equalizer 16, such as a Genlinx II GS9024 from the Gennum Corporation, Burlington, Ontario, Canada. Cable equalizer 16 is a high performance automatic cable equalizer capable of processing serial digital data rates from 30 to 622 Mb/s. Cable equalizer 16 receives either single-ended or differential serial data and outputs equalized differential signals at Positive Electrical Control Levels (PECL), e.g. 800 mV. Preferably, cable equalizer 16 provides up to 40dB of gain at 20 200 MHz, resulting in equalization of greater than 350m at

0 270Mb/s of Belden 8281 cable. The equalizer 16 also produces a signal level indicator.

A conventional test point 18 is preferably provided to allow testing of the eye signal.

5 The equalized signal from cable equalizer 16 is passed to serial digital reclocker 20, which automatically detects and locks onto the incoming differential signal. Reclocker 20 outputs a synchronized data signal which provides clock and data recovery for eliminating jitter, etc. Also, the laser driver is disabled if no proper clock and data are received.

10 Reclocker 20 may be operated in a manual mode where a particular data rate is specified or in an automatic mode in which the reclocker automatically cycles through the different SMPTE data rates and locks on to the correct one.

15 Reclocker 20 also produces a signal which indicates the data rate, which is processed in data rate and level encoder 22, as detailed below.

20 The synchronized signal from reclocker 20 passes to laser transmitter 24 where the electrical signal is converted to a corresponding laser signal and directed into fiber optic cable 25. A conventional automatic power control circuit is included to maintain a constant output power laser signal. While any suitable

0 laser transmitter may be used, the STX-12 from Optical
Communication Products, Inc., Chatsworth, CA is preferred. Data
rate and level encoder 22 receives a signal from reclocker 22, as
mentioned above. A signal level detector 26 (typically an
ICL7665CSA from the Maxim company) receives a an input signal
5 from cable equalizer 16, detects and analyzes the level of the
signal and passes that information on to data rate and level
encoder 22, typically an MC1455B available from the Motorola
company. Signals corresponding to the data rate and the degree of
lock are passed from data rate and level encoder 22 to Circuit
10 Board Indicator driver 23, typically a ULN2001A darlington array
which drives a panel having a row of light emitting diodes (as
seen in Figure 3) with indicia adjacent to each LED indicating
the meaning of the lighted LED. One of the top five LEDs
typically glows green when activated and shows the data rate,
15 e.g. 143, 177, 270, 360 and 540 Mb/s in use.

Three LEDs 32 indicate the signal level. Typically the top
LED 32 will show green when the signal level is at the optimum
level. The central LED 32 will glow yellow, indicating a
marginal, but generally useful, signal level. Bottom LED 32 will
20 glow red to indicate no signal or an unacceptably low signal
level.

0 A final LED 34 will glow green when the system is powered
and will be off when power is off.

Preferably, the system is voltage power protected and works
at 5 volts, as provided by power regulator 36 (typically a
L7805CV from the Motorola company) which receives AC/DC power
5 from power supply 38 at a voltage of 9 to 12V through
conventional wiring (not shown, for clarity) to the various
system components. Figure 2 is a block diagram of a receiver 38
for receiving information from fiber optic cable 25.

10 A laser carried signal from transmitter 10 is received at
laser receiver 40 via fiber optic cable 25 where an electrical
signal corresponding to the incoming signal is created. While any
suitable laser receiver may be used, the SRX-12 from Optical
Communications Products, Inc. is preferred. The signal is then
passed to reclocker 42, typically a GENLINX II GS9035 from the
15 Gennum corporation. Reclocker 42 includes a function selector
that automatically detects and locks onto the incoming data
signal. Information relating to the detected data rate and degree
of lock are passed onto data rate and lock encoder 48, as
described below.

20 The synchronized data signal from reclocker 42 is passed to
a coaxial cable driver 52 (typically a GS9028 from the Gennum

0 Corporation) that is designed to drive at least one 75 ohm co-
axial cable 54. The electrical data signal from cable 54 can be
directed to any suitable equipment, such as a monitor, editing or
post-production equipment, etc. Data rate and lock encoder 48
receives the data rate automatically selected at reclocker 42 and
5 information showing the degree of lock and encodes that
information for use by CBI driver 50. Typically, data rate and
lock encoder 48 may be an MC14555B decoder/demultiplexer from
Motorola.

10 CBI driver 50 typically includes a plurality of darlington
array pairs to drive an LED display. CBI driver 50 may be a
ULN2001AD device from SGS-Thomson Microelectronics. A plurality
of LEDs are provided to indicate the data rate being used.
Typically, five LEDs 56 are provided, each of which indicates one
data rate from a typical set including data rates of 143,
15 177, 270, 360 and 540 Mb/s. Indica alongside each LED indicates
which rate is symbolized by that LED. A second series 58 of LEDs
indicates lock and unlock. Typically, lock will be indicated by a
green LED, and unlock by a red LED.

20 A conventional power supply 62 furnishes 5 volt power to the
other components, typically from a 12 volt input 64. A final LED
60, grouped with the other LEDs will indicate power on by,

0 typically, a green LED. Both transmitter 10 and receiver 40
preferably have the same general housing configuration. Figure 3
shows a perspective view of a housing 70 for a typical
transmitter 10 while Figure 4 shows the back of housing 70.
Housing 70 has side walls 72, preferably parallel, a back wall
5 74, preferably sloping for ease of access, and a front wall 76.
Mounting flanges 78 are provided for mounting a plurality of
 housings 70 side-by-side in a rack. Alternatively, flanges 78 may
be secured to a sidewall 72, parallel to the sidewall, for
mounting on a professional video camera or the like. A coaxial
10 cable connector 80 and a fiber optic cable connector 82 are
provided on back face 74.

On the back surface, as seen in Figure 4, are located the
various informational diodes, including data rate diodes 30, one
of which will be lit to show one specific data rate, signal level
15 diodes one of which will be lit to indicate high, medium or low
signal level and a power LED 34 to indicate power on. Indica are
provided alongside each LED to indicate the parameter being
indicated, e.g. data rate numbers, "signal level", "power on",
etc.

20 Figure 5 shows a perspective view of a housing 86 for a
typical receiver 38 Housing 86 has side walls 88, preferably

0 parallel, a back wall 90, preferably sloping for ease of access,
and a back wall 92. Mounting flanges 94 are provided for mounting
a plurality of housings 86 side-by-side in a rack.

Alternatively, flanges 94 may be secured to a sidewall 88,
parallel to the sidewall, for mounting on a professional video
5 camera or the like. A coaxial cable connector 96 is provided for
the outgoing electrical signal on back face 90. A fiber optic
cable connector 98 is provided for the incoming optical signal.

On the back surface, as seen in Figure 6, are located the
various informational LEDs, including data rate LED 100, one of
10 which will be lit to show one specific data rate, and lock and
unlock diodes 102 one of which will be lit to indicate high lock
or unlock and a power LED 104 to indicate power on. Indica are
provided alongside each LED to indicate the parameter being
indicated, e.g. data rate numbers, "lock", "power on", etc.

15 Altogether, this is a compact, efficient system which
provides access to diagnostic and trouble shooting information
through the LED array and test points.

Other applications, variations and ramifications of this
invention will occur to those skilled in the art upon reading
20 this disclosure. Those are intended to be included within the
scope of this invention, as defined in the appended claims.
